It was discovered that, for vast classes of models, the average size of volatility is not constant but changes with time and is predictable. Autoregressive conditional heteroskedasticity (ARCH), generalized autoregressive conditional heteroskedasticity (GARCH) models and stochastic volatility models are the main tools used to model and forecast volatility.

A model can be defined by calling the `arch_model()` function. We can specify a model for the mean of the series: in this case `mean='Zero'` is an appropriate model. We can then specify the model for the variance: in this case `vol='ARCH'`. We can also specify the lag parameter for the ARCH model: in this case `p=15`. Note, in the `arch` library, the names of `p` and `q` parameters for ARCH/GARCH ...

The orthogonal models are particular F-GARCH models and thus are nested in the BEKK model. As a consequence, their properties follow from those of the BEKK model. In particular, it is obvious that the (G)O-GARCH model is covariance-stationary if the m univariate GARCH processes are themselves stationary. 2.3.

GARCH(1,1) Process • It is not uncommon that ρ needs to be very big in order to capture all the serial correlation in r^2_t . • The generalized ARCH or GARCH model is a parsimonious alternative to an ARCH(p) model. It is given by $\sigma^2_t = \omega + \alpha r^2_{t-1} + \beta \sigma^2_{t-1}$ (14) where the ARCH term is r^2_{t-1} and the GARCH term is σ^2_{t-1} .

NAGARCH. Nonlinear Asymmetric GARCH(1,1) (NAGARCH) is a model with the specification: $\sigma^2_t = \omega + (\alpha_+ - \alpha_-) r_{t-1} + \beta \sigma^2_{t-1}$, where $\alpha_+ \geq 0$, $\alpha_- \geq 0$, $\alpha_+ > \alpha_-$ and $(\alpha_+ + \alpha_-) < 1$, which ensures the non-negativity and stationarity of the variance process.. For stock returns, parameter α_+ is usually estimated to be positive; in this case, it reflects a phenomenon commonly referred to as the "leverage effect", signifying that negative ...

The GARCH model with t-distribution brings significant results in the ARCH and GARCH effects; Table 1 provides the output of the complete regression.

These results suggest that there is a quite strong persistence in volatility of the FTSE 100 index as the GARCH term has a coefficient above 0.9.

where. $\omega > 0$, $\alpha_1, \dots, \alpha_p, b_1, \dots, b_q \geq 0$, $\sum \alpha_i + \sum \beta_j < 1$. The GARCH model applies more weight to the more recent observations, thus allowing the model to quickly adapt to changing volatility regimes. The parameters of the model are determined via maximum likelihood estimation.
